

From Theory to Practice: Minwal's Biostatistics Mentorship Program

Project No 2.

Title:

Comparison of high-intensity laser and low-intensity laser therapy in patients with Lumbar Disc Herniation

Methods:

This study will involve sixty patients diagnosed with lumbar disc herniation, aged between 18 and 60 years, who will be recruited from a Teaching Hospital. The participants will be randomly assigned to three groups, with each group consisting of twenty patients.

- The first group will receive high-intensity therapeutic laser treatment combined with exercises.
- The second group will undergo low-level therapeutic laser treatment with exercises.
- The third group will be given placebo laser treatment alongside exercises.

Objective

The purpose of this study was to examine the efficacy of high-intensity laser therapy (HILT), low-level laser therapy (LLLT), and placebo. To illustrate the best method of laser treatment for patients with lumbar disc herniation.

Patient assessments will be conducted both before the start of treatment and after its completion, using the following tools:

the Visual Analog Scale (VAS),

Oswestry Disability Index,

From Theory to Practice: Minwal's Biostatistics Mentorship Program

Roland Morris Disability Questionnaire,
Schober Test
